

Capacitor Micro-IC

Overview

It is formed by two parallel metal layers and has a high k -dielectric between them. The bottom layer forms a small parasitic cap with the substrate. This type is the most widely used, because of the high capacitance per unit area. They are very similar to the MIMs caps but with an oxide layer between metals is usually made by interdigitating metal layers with the process oxide. So the capacitance is created in two. Transistors can be used as a cap using the thin oxide layer from the gate as an insulator. The Gate acts as the top plate and the Drain and Source as the bottom plate. They are also called MIMs. They use only one metal layer, relying on the side capacitance property and the matching is better than the MIMs caps. For example, in X-FAB technology the devices csf3 or csft4. Go. This kind of caps are still an object of study and development. Deep narrow pores are made in the silicon substrate to gain more surface and create high-density capacitor saving die area.

What is a decoupling capacitor and how do I know if I need one?

To compensate for slow power supplies, we use decoupling capacitors. Decoupling capacitors add fast "charge storage" near the IC. So when your micro switches the outputs, instead of drawing charge from the power supply, it will first draw from the capacitors. This will buy the power supply some time to adjust to the changing demands.
